14: Dimensionality Reduction (PCA)

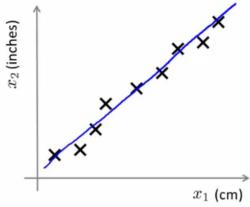

Previous Next Index

Motivation 1: Data compression

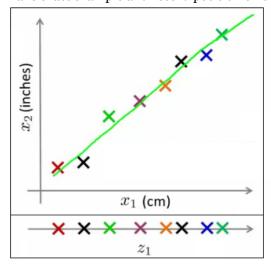

- $\bullet \ \ \text{Start talking about a second type of unsupervised learning problem -} \ \textbf{dimensionality reduction} \\$
 - Why should we look at dimensionality reduction?

Compression

- Speeds up algorithms
- Reduces space used by data for them
- What is dimensionality reduction?
 - o So you've collected many features maybe more than you need
 - Can you "simply" your data set in a rational and useful way?
 - o Example
 - Redundant data set different units for same attribute
 - Reduce data to 1D (2D->1D)

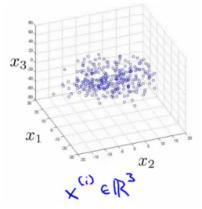

- Example above isn't a perfect straight line because of round-off error
- Data redundancy can happen when different teams are working independently
 - Often generates redundant data (especially if you don't control data collection)
- o Another example
 - Helicopter flying do a survey of pilots (x1 = skill, x2 = pilot enjoyment)
 - These features may be highly correlated
 - This correlation can be combined into a single attribute called aptitude (for example)
- What does dimensionality reduction mean?
 - In our example we plot a line
 - Take exact example and record position on that line

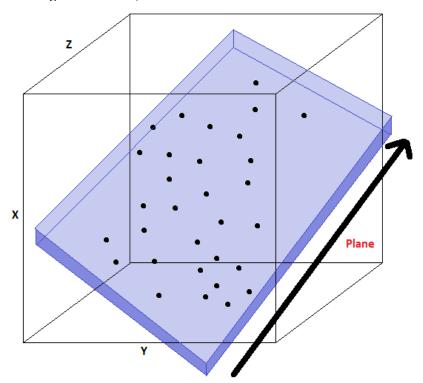

• So before x¹ was a 2D feature vector (X and Y dimensions)

- Now we can represent x¹ as a 1D number (Z dimension)
- So we approximate original examples
 - Allows us to half the amount of storage
 - Gives lossy compression, but an acceptable loss (probably)
 - The loss above comes from the rounding error in the measurement, however
- Another example 3D -> 2D
 - o So here's our data

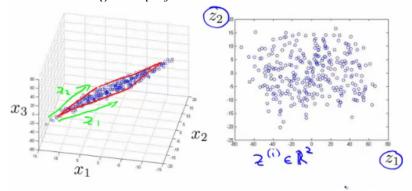

- Maybe all the data lies in one plane
 - This is sort of hard to explain in 2D graphics, but that plane may be aligned with one of the axis
 - Or or may not...
 - Either way, the plane is a small, a constant 3D space
 - In the diagram below, imagine all our data points are sitting "inside" the blue tray (has a dark blue exterior face and a light blue inside)

- Because they're all in this relative shallow area, we can basically ignore one of the dimension, so we draw two new lines (z1 and z2) along the x and y planes of the box, and plot the locations in that box
- i.e. we loose the data in the z-dimension of our "shallow box" (NB "z-dimensions" here refers to the dimension relative to the box (i.e it's depth) and NOT the z dimension of the axis we've got drawn above) but because the box is shallow it's OK to lose this. Probably....

• Plot values along those projections

- o So we've now reduced our 3D vector to a 2D vector
- In reality we'd normally try and do 1000D -> 100D

Motivation 2: Visualization

- It's hard to visualize highly dimensional data
 - o Dimensionality reduction can improve how we display information in a tractable manner for human consumption
 - Why do we care?
 - Often helps to develop algorithms if we can understand our data better
 - Dimensionality reduction helps us do this, see data in a helpful
 - Good for explaining something to someone if you can "show" it in the data
- Example;
 - o Collect a large data set about many facts of a country around the world

						Mean	
		Per capita			Poverty	household	
	GDP	GDP	Human		Index	income	
	(trillions of	(thousands	Develop-	Life	(Gini as	(thousands	
Country	US\$)	of intl. \$)	ment Index	expectancy	percentage)	of US\$)	
Canada	1.577	39.17	0.908	80.7	32.6	67.293	
China	5.878	7.54	0.687	73	46.9	10.22	
India	1.632	3.41	0.547	64.7	36.8	0.735	
Russia	1.48	19.84	0.755	65.5	39.9	0.72	
Singapore	0.223	*56.69	0.866	80	42.5	67.1	
USA	14.527	46.86	0.91	78.3	40.8	84.3	

- So
 - $x_1 = GDP$
 - ...
 - x_6 = mean household
- Say we have 50 features per country
- How can we understand this data better?
 - Very hard to plot 50 dimensional data
- o Using dimensionality reduction, instead of each country being represented by a 50-dimensional feature vector

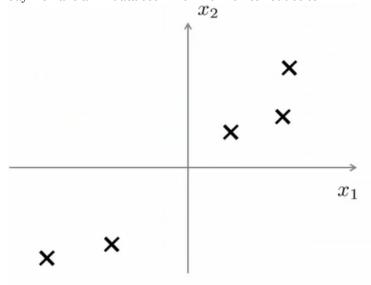

• Come up with a different feature representation (z values) which summarize these features

Country	z_1	z_2
Canada	1.6	1.2
China	1.7	0.3
India	1.6	0.2
Russia	1.4	0.5
Singapore	0.5	1.7
USA	2	1.5

- o This gives us a 2-dimensional vector
 - Reduce 50D -> 2D
 - Plot as a 2D plot
- Typically you don't generally ascribe meaning to the new features (so we have to determine what these summary values mean)
 - e.g. may find horizontal axis corresponds to overall country size/economic activity
 - and y axis may be the per-person well being/economic activity
- So despite having 50 features, there may be two "dimensions" of information, with features associated with each
 of those dimensions
 - It's up to you to asses what of the features can be grouped to form summary features, and how best to do that (feature scaling is probably important)
- Helps show the two main dimensions of variation in a way that's easy to understand

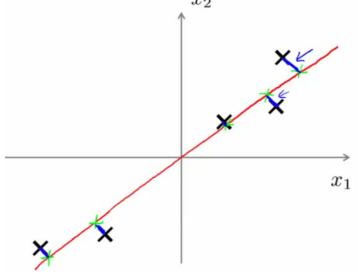

Principle Component Analysis (PCA): Problem Formulation

- For the problem of dimensionality reduction the most commonly used algorithm is PCA
 - Here, we'll start talking about how we formulate precisely what we want PCA to do
- So
 - o Say we have a 2D data set which we wish to reduce to 1D

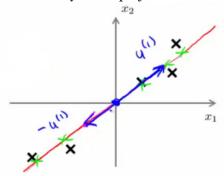

- o In other words, find a single line onto which to project this data
 - How do we determine this line?
 - The distance between each point and the projected version should be small (blue lines below are short)

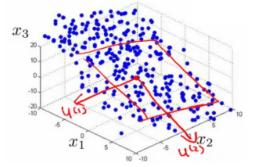

- PCA tries to find a lower dimensional surface so the sum of squares onto that surface is minimized
- The blue lines are sometimes called the **projection error**
 - PCA tries to find the surface (a straight line in this case) which has the minimum projection error

- As an aside, you should normally do mean normalization and feature scaling on your data before PCA
- A more formal description is
 - For 2D-1D, we must find a vector u⁽¹⁾, which is of some dimensionality
 - Onto which you can project the data so as to minimize the projection error

- u⁽¹⁾ can be positive or negative (-u⁽¹⁾) which makes no difference
 - Each of the vectors define the same red line
- In the more general case
 - o To reduce from nD to kD we
 - Find k vectors $(\mathbf{u}^{(1)}, \mathbf{u}^{(2)}, \dots \mathbf{u}^{(k)})$ onto which to project the data to minimize the projection error
 - So lots of vectors onto which we project the data
 - Find a set of vectors which we project the data onto the linear subspace spanned by that set of vectors
 - We can define a point in a plane with k vectors
 - ∘ e.g. 3D->2D
 - Find pair of vectors which define a 2D plane (surface) onto which you're going to project your data
 - Much like the "shallow box" example in compression, we're trying to create the shallowest box possible (by defining two of it's three dimensions, so the box' depth is minimized)

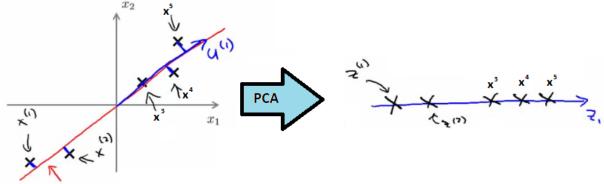

- How does PCA relate to linear regression?
 - PCA is **not** linear regression

- Despite cosmetic similarities, very different
- For linear regression, fitting a straight line to minimize the straight line between a point and a squared line
 - NB VERTICAL distance between point
- For PCA minimizing the magnitude of the shortest orthogonal distance
 - Gives very different effects
- More generally
 - With linear regression we're trying to predict "y"
 - With PCA there is no "y" instead we have a list of features and all features are treated equally
 - If we have 3D dimensional data 3D->2D
 - Have 3 features treated symmetrically

PCA Algorithm

- Before applying PCA must do data preprocessing
 - Given a set of m unlabeled examples we must do
 - Mean normalization
 - Replace each x_i^1 with $x_i \mu_i$,
 - In other words, determine the mean of each feature set, and then for each feature subtract the mean from the value, so we re-scale the mean to be o
 - Feature scaling (depending on data)
 - If features have very different scales then scale so they all have a comparable range of values
 - e.g. x_i^i is set to $(x_i \mu_i) / s_i$
 - Where s_i is some measure of the range, so could be
 - Biggest smallest
 - Standard deviation (more commonly)
- With preprocessing done, PCA finds the lower dimensional sub-space which minimizes the sum of the square
 - In summary, for 2D->1D we'd be doing something like this;

- Need to compute two things;
 - Compute the **u vectors**
 - The new planes
 - Need to compute the **z vectors**
 - z vectors are the new, lower dimensionality feature vectors
- A mathematical derivation for the u vectors is very complicated
 - o But once you've done it, the procedure to find each u vector is not that hard

Algorithm description

- Reducing data from *n*-dimensional to k-dimensional
 - Compute the covariance matrix

$$\Sigma = \frac{1}{m} \sum_{i=1}^{n} (x^{(i)}) (x^{(i)})^{T}$$

- This is commonly denoted as Σ (greek upper case sigma) NOT summation symbol
- $\Sigma = \text{sigma}$
 - This is an [n x n] matrix
 - Remember than x¹ is a [n x 1] matrix

■ In MATLAB or octave we can implement this as follows;

$$sigma = (1/m) * (X' * X)$$

- \circ Compute eigenvectors of matrix Σ
 - [U,S,V] = svd(sigma)
 - svd = singular value decomposition
 - More numerically stable than eig
 - eig = also gives eigenvector
- o U,S and V are matrices
 - U matrix is also an [n x n] matrix
 - Turns out the columns of U are the u vectors we want!
 - So to reduce a system from n-dimensions to k-dimensions
 - Just take the first *k-vectors* from U (first k columns)

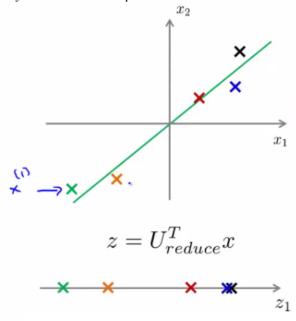

$$U = \begin{bmatrix} | & | & | & | \\ u^{(1)} & u^{(2)} & \dots & u^{(n)} \\ | & | & | \end{bmatrix} \in \mathbb{R}^{n \times n}$$

- Next we need to find some way to change x (which is n dimensional) to z (which is k dimensional)
 - (reduce the dimensionality)
 - Take first k columns of the u matrix and stack in columns
 - n x k matrix call this U_{reduce}
 - We calculate z as follows
 - $\mathbf{z} = (\mathbf{U}_{\text{reduce}})^T * \mathbf{x}$
 - So [k x n] * [n x 1]
 - Generates a matrix which is
 - k*1
 - If that's not witchcraft I don't know what is!
- Exactly the same as with supervised learning except we're now doing it with unlabeled data
- So in summary
 - Preprocessing
 - Calculate sigma (covariance matrix)
 - Calculate eigenvectors with svd
 - $\circ~$ Take k vectors from U (U_{reduce}= U(:,1:k);)
 - \circ Calculate z (z = U_{reduce}' * x;)
- No mathematical derivation
 - Very complicated
 - But it works

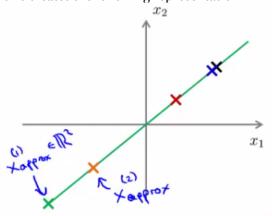

Reconstruction from Compressed Representation

- Earlier spoke about PCA as a compression algorithm
 - If this is the case, is there a way to **decompress** the data from low dimensionality back to a higher dimensionality format?
- Reconstruction

• Say we have an example as follows

- We have our examples (x1, x2 etc.)
- o Project onto z-surface
- Given a point z¹, how can we go back to the 2D space?
- Considering
 - \circ z (vector) = $(\mathbf{U}_{\text{reduce}})^T * \mathbf{x}$
- To go in the opposite direction we must do
 - $\circ x_{approx} = U_{reduce} * z$
 - To consider dimensions (and prove this really works)
 - $U_{reduce} = [n \times k]$
 - z[k*1]
 - So
 - $x_{approx} = [n \times 1]$
- So this creates the following representation

• We lose some of the information (i.e. everything is now perfectly on that line) but it is now projected into 2D space

Choosing the number of Principle Components

- How do we chose *k* ?
 - k = number of **principle components**
 - o Guidelines about how to chose k for PCA
- To chose k think about how PCA works

• PCA tries to minimize averaged squared projection error

 Total variation in data can be defined as the average over data saying how far are the training examples from the origin

• When we're choosing k typical to use something like this

$$\frac{\frac{1}{m} \sum_{i=1}^{m} \|x^{(i)} - x_{approx}^{(i)}\|^2}{\frac{1}{m} \sum_{i=1}^{m} \|x^{(i)}\|^2} \le 0.01 \tag{1\%}$$

- o Ratio between averaged squared projection error with total variation in data
 - Want ratio to be small means we retain 99% of the variance
- o If it's small (o) then this is because the numerator is small
 - The numerator is small when $x^i = x_{approx}^i$
 - i.e. we lose very little information in the dimensionality reduction, so when we decompress we regenerate the same data
- So we chose k in terms of this ratio
- · Often can significantly reduce data dimensionality while retaining the variance
- · How do you do this

Algorithm:

Try PCA with
$$k=1$$

Compute
$$U_{reduce}, z^{(1)}, z^{(2)},$$

$$\dots, z^{(m)}, x_{approx}^{(1)}, \dots, x_{approx}^{(m)}$$

Check if

$$\frac{\frac{1}{m} \sum_{i=1}^{m} \|x^{(i)} - x_{approx}^{(i)}\|^2}{\frac{1}{m} \sum_{i=1}^{m} \|x^{(i)}\|^2} \le 0.01?$$

Advice for Applying PCA

- Can use PCA to speed up algorithm running time
 - Explain how
 - And give general advice

Speeding up supervised learning algorithms

- Say you have a supervised learning problem
 - Input x and y
 - x is a 10 000 dimensional feature vector
 - e.g. 100 x 100 images = 10 000 pixels
 - Such a huge feature vector will make the algorithm slow
 - With PCA we can reduce the dimensionality and make it tractable
 - How
 - 1) Extract xs
 - So we now have an unlabeled training set
 - 2) Apply PCA to x vectors
 - So we now have a reduced dimensional feature vector z
 - 3) This gives you a new training set
 - Each vector can be re-associated with the label
 - 4) Take the reduced dimensionality data set and feed to a learning algorithm
 - Use y as labels and z as feature vector

- 5) If you have a new example map from higher dimensionality vector to lower dimensionality vector, then feed into learning algorithm
- PCA maps one vector to a lower dimensionality vector
 - $\circ x \rightarrow z$
 - Defined by PCA **only** on the training set
 - The mapping computes a set of parameters
 - Feature scaling values
 - U_{reduce}
 - Parameter learned by PCA
 - Should be obtained only by determining PCA on your training set
 - o So we use those learned parameters for our
 - Cross validation data
 - Test set
- Typically you can reduce data dimensionality by 5-10x without a major hit to algorithm

Applications of PCA

- Compression
 - Why
 - Reduce memory/disk needed to store data
 - Speed up learning algorithm
 - How do we chose k?
 - % of variance retained
- Visualization
 - \circ Typically chose k = 2 or k = 3
 - Because we can plot these values!
- One thing often done wrong regarding PCA
 - A bad use of PCA: Use it to prevent over-fitting
 - Reasoning
 - If we have xⁱ we have n features, zⁱ has k features which can be lower
 - If we *only* have k features then maybe we're less likely to over fit...
 - This doesn't work
 - BAD APPLICATION
 - Might work OK, but not a good way to address over fitting
 - Better to use regularization
 - PCA throws away some data without knowing what the values it's losing
 - Probably OK if you're keeping most of the data
 - But if you're throwing away some crucial data bad
 - So you have to go to like 95-99% variance retained
 - So here regularization will give you AT LEAST as good a way to solve over fitting
- A second PCA myth
 - Used for compression or visualization good
 - Sometimes used
 - Design ML system with PCA from the outset
 - But, what if you did the whole thing without PCA
 - See how a system performs without PCA
 - ONLY if you have a reason to believe PCA will help should you then add PCA
 - PCA is easy enough to add on as a processing step
 - Try without first!
